Constraints of Second-Order Vanishing Moments on Lattice Structures for Non-separable Orthogonal Symmetric Wavelets

Atsuyuki ADACHI†, Nonmember, Shogo MURAMATSU‡, Member, and Hisakazu KIKUCHI†, Fellow

SUMMARY In this paper, a design method of two-dimensional (2-D) orthogonal symmetric wavelets is proposed by using a lattice structure for multi-dimensional (M-D) linear-phase paraunitary filter banks (LPPUFB), which the authors have proposed as a previous work and then modified by Lu Gan et al. The derivation process for the constraints on the second-order vanishing moments is shown and some design examples obtained through optimization with the constraints are exemplified. In order to verify the significance of the constraints, some experimental results are shown for Lena and Barbara images.

key words: wavelets, orthogonal transforms, non-separable filter banks, vanishing moments, video coding

1. Introduction

Still picture codec standards, such as JPEG and JPEG2000, and motion picture codec standards, such as MPEG-1/2 and H.264/AVC, employ transform coding techniques as basic components for reducing spatial redundancy [1]–[3]. The coding performance of whole system is severely influenced by the choice of the transform.

JPEG and MPEG-1/2 consist of a 8x8 two-dimensional (2-D) discrete cosine transform (DCT). DCT is known as a quasi-optimal transform for the first-order autoregressive process with a correlation close to 1. As well, the transform kernel is defined by the cosine function and efficient computation is available through some fast algorithms. From these reasons, DCT has favourably been used in both of still and motion picture codecs. The independent block processing, however, makes block boundaries visible and the large basis images of high frequency components causes mosquito noise for very low bit-rates. JPEG2000 tries to solve these problems by introducing discrete wavelet transforms (DWTs). The DWTs contribute not only to gain coding performances and realize the spatial scalability, but also to reduce the blocking artifacts and the mosquito noise, because of their overlapping basis images and their different sizes suitable for different frequency components.

It is well known that there is no 1-D 2-channel filter bank which simultaneously satisfies all of the overlapping, linear-phase and paraunitary (i.e. orthogonal) property [4]. It is also true for separable 2-D 2 x 2-channel filter banks, which are employed in JPEG2000. Non-separable 2 x 2-channel filter banks, however, can simultaneously satisfy all of the previous properties. As well, image and video processing requires us to pay attention to frequency support of original signals because it may be non-separable [5]. From these backgrounds, M-D non-separable systems which simultaneously satisfy the orthogonal, overlapping and linear-phase property have been considered by several researches so far.

The authors also proposed non-separable transforms by using 2 x 2-channel linear-phase paraunitary filter banks (LPPUFBs) in the lattice structure as a previous work [6]. Furthermore, Lu Gan et al. showed the way of reducing the number of parameters to be optimized while preserving the class [7]. Since the orthogonal, overlapping, and linear-phase property are guaranteed, the lattice structure is convenient in terms of design and implementation. Additionally, we can construct 2 x 2-decomposition symmetric orthogonal DWTs by hierarchically applying the lattice structure. However, it has not been clarified how to design DWTs with vanishing moments through the lattice structure. Although Stanhill et al. exemplified a design procedure of such DWTs [8], [9], no constraint on design parameters in closed form has not been shown. For the 1-D case, the article [10] showed a design procedure of M-band orthogonal symmetric wavelets with lattice structures of second-order vanishing moments. In this work, it is shown that the constraints can be obtained in closed form of design parameters for the 2x2-channel 2-D lattice structure by using the similar approach to the 1-D lattice. Indeed, we design filter banks with our new method, and through an experiment on image coding, we verify the significance.

Organization of this paper is as follows: Section 2 reviews the design method of LPPUFBs based on lattice structure. Section 3 derives the constraints on the second-order vanishing moments for the lattice structure. Section 4 shows the results of the optimal design, followed by conclusions in Sect. 5.

2. Review of M-D Orthogonal Symmetric DWTs

In this section, we review M-D LPPUFBs based on a lattice structure, which the authors have proposed as a previous work and then Lu Gan et al. improved. Then, orthogonal symmetric non-separable DWTs are summarized.

It is well known that there is no 1-D 2-channel filter bank which simultaneously satisfies the overlapping, linear-phase and paraunitary (i.e. orthogonal) property [4]. This limitation is taken over by 2-D 2 x 2-channel filter banks.
Non-separable systems, however, allow us to design $2 \times 2$-channel LPPUFBs with overlapping bases, which can simultaneously decompose a picture into vertical and horizontal directions [6], [7], [9].

As a previous work, we have proposed a design procedure of M-D LPPUFBs based on a lattice structure [6]. Furthermore, Lu Gan et al. showed the way of reducing the number of parameters to be optimized while preserving the class [7]. Figure 1 shows a parallel structure of $2 \times 2$-channel filter banks, where $\downarrow \mathbf{M}$ and $\uparrow \mathbf{M}$ are respectively the downsampler and upsampler with factor $\mathbf{M} = \left( \begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix} \right)$. $H_k(z)$ and $F_k(z)$ are respectively 2-D non-separable analysis and synthesis filters. A lattice structure of the analysis part of $2 \times 2$-channel LPPUFB is given in Fig. 2, where $X(z)$ is input signal, $Y_k(z)$ is the $k$-th subband signal, $z_0$ is the delay element of $d$-th dimension, $\mathbf{U}_0^{(0)}$ and $\mathbf{W}_d^{(d)}$ are arbitrary $2 \times 2$-decomposition orthogonal matrices, and $K$ is a scaling factor given by $K = 2^{-(N_0 + N_1)}$. From the paraunitary property, the impulse responses of synthesis filters $F_k(z)$ are given as the 180°-rotated version of the counterpart analysis filters $H_k(z)$.

A polyphase matrix of a $2 \times 2$-channel LPPUFB is given by

$$
\mathbf{E}(z_0, z_1) = \left( \prod_{n=1}^{N_1} \mathbf{R}_n^{(1)} \right) \left( \prod_{n=0}^{N_0} \mathbf{Q}(z_1) \right) \left( \prod_{n=0}^{N_6} \mathbf{R}_n^{(0)} \right) \mathbf{Q}(z_0) \mathbf{E}_0 \tag{1}
$$

where $\prod_{n=1}^{N_1} \mathbf{A}_n = \mathbf{A}_1 \mathbf{A}_{N-1} \cdots \mathbf{A}_2 \mathbf{A}_1$, and

$$
\mathbf{R}_d^{(d)} = \begin{cases} 
\left( \begin{array}{cc}
\mathbf{W}_n^{(d)} & \mathbf{O}_2 \\
\mathbf{O}_2 & \mathbf{I}_2 
\end{array} \right), & d \in \{0, 1\} \\
\left( \begin{array}{cc}
\mathbf{W}_n^{(0)} & \mathbf{O} \\
\mathbf{O} & \mathbf{U}_n^{(0)} 
\end{array} \right), & d = 0
\end{cases} \tag{2}
$$

In this section, we derive the constraints on the second-order vanishing moments for the lattice structure.

3. Derivation of Constraints on the 2nd-Order Vanishing Moments

In this section, we derive the constraints on the second-order vanishing moments for the lattice structure.

3.1 Vanishing Moments of the 2-D DWTs

The article [8] describes the condition of vanishing moments of 2-D non-separable DWTs. The condition of the first-order vanishing moments is given by

$$
H_{00}(z_0, z_1) \left( \frac{z_0}{z_1} \right) e\left( \frac{-1}{2} \right) = 0 \tag{5}
$$

and, that of the second-order vanishing moments is given by

$$
\frac{\partial}{\partial z_0} H_{00}(z_0, z_1) \left( \frac{z_0}{z_1} \right) e\left( \frac{-1}{2} \right) = 0, \quad d \in \{0, 1\} \tag{6}
$$

The article [9] shows a design example of 2-D orthogonal symmetric DWTs with maximum vanishing moments.
The design parameters, however, are not constrained directly and, thus it was difficult to design the filters systematically. The article [10] shows a design method of a lattice structure for 1-D M-channel LPPUFBs with the second-order vanishing moments. In this work, by using the similar approach, we consider constraints of the second-order vanishing moments imposed for constructing 2-D LPPUFBs.

3.2 Constraints for 2-D Non-separable Lattice Structure

In the lattice structure shown in Fig. 2, the constraints on the first-order vanishing moments in Eq. (5) is rewritten in terms of the design parameters by

\[
W_0^{[0]} = \left( \prod_{n_1=1}^{N_1} W_{n_1}^{[1]} \right) \cdot \left( \prod_{n_0=1}^{N_0} W_{n_0}^{[1]} \right)
\]

[6]. As well, the constraints on the second-order vanishing moments are derived by

\[
C_0 (1) + \frac{1}{2} (0) = 0,
\]

\[
C_1 (1) + \frac{1}{2} (0) = 0,
\]

where

\[
C_0 = \left( \prod_{n_1=1}^{N_1} W_{n_1}^{[1]} \right) \cdot \sum_{k_1=1}^{N_1} \left( \prod_{n_0=1}^{N_0} W_{n_0}^{[1]} \right) \cdot T_0^{[0]},
\]

\[
C_1 = \sum_{k_1=1}^{N_1} \left( \prod_{n_1=1}^{N_1} W_{n_1}^{[1]} \right) \cdot U_0^{[0]}.
\]

The above constraints are newly derived in this paper. In the following section, let us detail the derivation.

3.3 Derivation of Constraints on the 2nd-Order Vanishing Moments

In order to show the derivation process of the constraints in Eqs. (8)–(11), let us begin with represent the lowpass filter \(H_{00}(\zeta_0, \zeta_1)\) in terms of the poly-phase matrix \(E(\zeta_0, \zeta_1)\). Then, we obtain

\[
H_{00}(\zeta_0, \zeta_1) = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} E(\zeta_0, \zeta_1) d(\zeta_0, \zeta_1)
\]

\[
= \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} \left( \prod_{n_1=1}^{N_1} R_{n_1}^{[1]} Q(\zeta_1) \right)
\]

\[
\times \sum_{n_0=1}^{N_0} R_{n_0}^{[0]} Q(\zeta_0) R_{n_0}^{[0]} E_0 d(\zeta_0, \zeta_1),
\]

where

\[
d(\zeta_0, \zeta_1) = \begin{pmatrix} 1 \\ \zeta_0^{-1} \\ \zeta_1^{-1} \\ \zeta_0^{-1} \zeta_1^{-1} \end{pmatrix}.
\]

As well, the partial derivatives with respect to each variable are given by

\[
\frac{\partial}{\partial \delta_0} H_{00}(\zeta_0, \zeta_1)
\]

\[
= \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} \left( \prod_{n_1=1}^{N_1} R_{n_1}^{[1]} Q(\zeta_1) \right)
\]

\[
\times \sum_{n_0=1}^{N_0} R_{n_0}^{[0]} Q(\zeta_0) R_{n_0}^{[0]} E_0 d(\zeta_0, \zeta_1),
\]

\[
\frac{\partial}{\partial \zeta_1} H_{00}(\zeta_0, \zeta_1)
\]

\[
= \begin{pmatrix} 1 & 0 & 0 \end{pmatrix} \left( \prod_{n_1=1}^{N_1} R_{n_1}^{[1]} Q(\zeta_1) \right)
\]

\[
\times \sum_{n_0=1}^{N_0} R_{n_0}^{[0]} Q(\zeta_0) R_{n_0}^{[0]} E_0 d(\zeta_0, \zeta_1),
\]

respectively, where \(\delta[n]\) is the sequence which equals one when \(n = 0\), and zero otherwise.

Let \(\zeta_d \in \{-1, 1\}\). Substituting \(\zeta_d = \zeta_d\), we can simplify Eqs. (13) and (14) to

\[
\frac{\partial}{\partial \delta_0} H_{00}(\zeta_0, \zeta_1)
\]

\[
= -\zeta_0 \begin{pmatrix} 1 & 0 \end{pmatrix} \left( N_0 I - C_0 \right) E_0 d(\zeta_0, \zeta_1) - \frac{1}{2} \zeta_0^2 (1 + \zeta_1),
\]

(15)

\[
\frac{\partial}{\partial \zeta_1} H_{00}(\zeta_0, \zeta_1)
\]

\[
= -\zeta_1 \begin{pmatrix} 1 & 0 \end{pmatrix} \left( N_1 I - C_1 \right) E_0 d(\zeta_0, \zeta_1) - \frac{1}{2} \zeta_1^2 (1 + \zeta_0),
\]

(16)

respectively, where we used some properties shown in Appendix A and the constraint of the first-order vanishing moments in Eq. (7) for simplifying the second term in the right-hand side.

Finally, using the following relations:
3.4 Number of Control Parameters

The number of parameters are discussed in the followings. The polyphase matrix of order \( (N_0, N_1) \) is composed of \( N_0 + N_1 + 2 \) orthonormal matrices of size \( 2 \times 2 \). Thus, the total number of control parameters are \( N_0 + N_1 + 2 \) in the form of rotation angles. Let us see how the second-order vanishing moment constraints reduce the number of design parameters and the number becomes \( N_0 + N_1 - 3 \). Our discussion here temporarily restricts for all orthonormal matrices to be in the following rotation form:

\[
T[\theta] = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix},
\]

(21)

3.4.1 Triangle Analysis \[10\]

Let \( a = (1, 0)^T \) and \( \omega = (0, 0)^T \). Then, Eqs. (8) and (9) can be rewritten as follows:

\[
a_d + \sum_{k_d=1}^{N_1-N_0} \prod_{n_d=1}^{N_0} W_{n_d}^{(d)} a_d + \frac{1}{2} V_0^{(d)} V_1^{(d)} W_2^{(d)} a_d = o, \quad d \in \{0, 1\},
\]

(22)

where

\[
a_d = \left( \prod_{n_d=1}^{N_0} W_{n_d}^{(0)} \right) \left( \prod_{n_1=1}^{N_1} W_{n_1}^{(1)} \right)^T a,
\]

(23)

\[
a_1 = \left( \prod_{n_1=1}^{N_1} W_{n_1}^{(1)} \right)^T a,
\]

(24)

\[
V^{(0)} = \begin{cases} \left[ \frac{\pi}{2} \prod_{n_1=1}^{N_1} W_{n_1}^{(1)} \right]_{n_0=1}^{N_0} \left[ \prod_{n_0=3}^{N_0} W_{n_0}^{(0)} \right]_{n_1=1}^{N_1}, & N_0 \leq 2 \\ \left[ \frac{\pi}{2} \prod_{n_1=1}^{N_1} W_{n_1}^{(1)} \right]_{n_0=1}^{N_0}, & N_0 > 2 \end{cases}
\]

(25)

Expressing the above relations together, the constraints in Eqs. (8) and (9) are given.

3.4.2 Example of Minimal Support Case

For minimal support case, i.e. \( N_0 = N_1 = 2 \), we have three vectors \( x_1^{(d)} = a_d, x_2^{(d)} = W_1^{(d)} x_1^{(d)} \) and \( x_3^{(d)} = U_0^{(d)} V_1^{(d)} W_2^{(d)} x_2^{(d)} \) in Eq. (22) for each \( d \in \{0, 1\} \), where \( \|x_1^{(d)}\| = 1 \) and \( \|x_2^{(d)}\| = 1/2 \). These vectors should constitute a bilateral triangle. The rotation angles from \( x_1^{(d)} \) to \( x_2^{(d)} \) and from \( x_2^{(d)} \) to \( x_3^{(d)} \) are respectively given as follows:

\[
\theta_1^{d=2} = (-1)^{\sigma_d} \left( \pi - 2 \sin^{-1} \left( \frac{\|x_3^{(d)}\|}{2 \|x_1^{(d)}\|} \right) \right),
\]

(26)

\[
\theta_2^{d=3} = (-1)^{\sigma_d} \left( \pi - \cos^{-1} \left( \frac{\|x_2^{(d)}\|}{2 \|x_1^{(d)}\|} \right) \right),
\]

(27)

where \( \sigma_d \in (0, 1) \) is the sign, which controls the rotational direction.

Thus, matrices \( W_1^{(0)} \) and \( W_1^{(1)} \) are determined as

\[
W_1^{(0)} = T[\theta_1^{d=2}] T[\theta_2^{d=3}], \quad d \in \{0, 1\}.
\]

(28)

From the relation \( x_3^{(d)} = \|x_3^{(d)}\| T[\theta_2^{d=3}] x_2^{(d)} \), we see that \( W_2^{(d)} \) is also imposed the following condition:

\[
W_2^{(d)} = V^{(d)} U_0^{(d)} T[\theta_2^{d=3}], \quad d \in \{0, 1\}.
\]

(29)

Since \( V^{(1)} = I \) and \( V^{(0)} = T[\pi/2] W_1^{(0)} W_1^{(1)} \), \( W_1^{(1)} \) and \( W_1^{(0)} \) are determined in the following order:

\[
W_1^{(0)} = U_0^{(0)} T[\theta_2^{d=3}], \quad W_1^{(1)} = W_2^{(0)} T[\pi/2] U_0^{(0)} T[\theta_2^{d=3}].
\]

(30)

Note that \( U_0^{(0)} \) is fixed for the first-order vanishing moment. Therefore, we are allowed to control only \( U_0^{(0)} \).

3.4.3 Case for \( N_0, N_1 > 2 \)

For \( N_0, N_1 > 2 \), Eq. (22) can be seen as a triangle consisting
of the three vectors defined by
\[ x_1^{[d]} = a_d, \quad x_2^{[d]} = W_1^{[d]} x_1^{[d]}, \quad x_3^{[d]} = \left( I + \sum_{k_d=1}^{N_d-3} \prod_{n_d=3}^{N_d-k_d} W_n^{[d]} + \frac{1}{2} U_0^{[0]} V^{[d]} \right) W_2^{[d]} x_2^{[d]} \]
and
\[ x_3^{[d]} = \left( I + \sum_{k_d=1}^{N_d-3} \prod_{n_d=3}^{N_d-k_d} W_n^{[d]} + \frac{1}{2} U_0^{[0]} V^{[d]} \right) x_2^{[d]} + \frac{1}{2} \sum_{n_d=3}^{N_d-k_d} W_n^{[d]} \]
(33)
The last equation uses the fact that the adopted orthonormal matrices are all in the form in Eq. (21).

The length of vector \( x_3^{[d]} \) varies and is given by
\[ ||x_3^{[d]}|| = \sqrt{c_d(\Theta)^2 + s_d(\Theta)^2}, \]
(34)
where we used the fact that \( x_2^{[d]} \) is a rotation of \( a \). Equivalently, we have
\[ ||x_3^{[d]}|| = \sqrt{c_d(\Theta)^2 + s_d(\Theta)^2}, \]
(35)
where \( \Theta \) is a set of the rotation angle parameters and
\[ c_d(\Theta) = 1 + \sum_{k_d=1}^{N_d-3} \cos \left( \sum_{n_d=3}^{N_d-k_d} \Theta_n^{[d]} \right) + \frac{1}{2} \cos \left( \Theta_U^{[0]} + \Theta_V^{[d]} \right), \]
(36)
\[ s_d(\Theta) = \sum_{k_d=1}^{N_d-3} \sin \left( \sum_{n_d=3}^{N_d-k_d} \Theta_n^{[d]} \right) + \frac{1}{2} \sin \left( \Theta_U^{[0]} + \Theta_V^{[d]} \right), \]
(37)
where \( \Theta_n^{[d]} \) and \( \Theta_U^{[0]} \) are the rotation angles of matrices \( W_n^{[d]} \) and \( U_0^{[0]} \), respectively. We also define
\[ \Theta_{n}^{[1]} = \sum_{n_{i}=1}^{N_1} \Theta_{n_{i}}^{[1]}, \quad \Theta_{n}^{[0]} = \frac{\pi}{2} + \sum_{n_{i}=1}^{N_1} \Theta_{n_{i}}^{[0]} + \sum_{n_2=3}^{N_d} \Theta_{n_2}^{[0]} \]
Note that \( ||x_3^{[d]}|| \) is independent of the choice of \( W_1^{[d]} \) and \( W_2^{[d]} \), which will be fixed later.

It here should be noted that the length of vector \( x_3^{[d]} \) must satisfy the following triangle inequality:
\[ 0 \leq ||x_3^{[d]}|| \leq ||x_1^{[d]}|| + ||x_2^{[d]}|| = 2. \]
(38)
For \( N_d = 3 \), this condition is always satisfied with \( ||x_3^{[d]}|| \leq 3/2 \), whereas the free parameters should be constrained to hold this condition for \( N_d > 3 \) [10].

Let \( U_0^{[0]} \) and \( W_n^{[d]} \) for \( n_d = 3, 4, \cdots, N_d, d \in (0, 1) \) be free to be chosen. The design process starts to calculate the length \( ||x_3^{[d]}|| \) for direction \( d = 1 \) then proceed to direction \( d = 0 \) after the process for \( d = 1 \) is done. Provided the condition in Eq. (38) holds, we can solve the rotation angles among the vectors as
\[ \Theta_{n-2}^{[d]} = (-1)^{n-2} \left( \pi - 2 \sin^{-1} \left( \frac{||x_3^{[d]}||}{2} \right) \right), \]
\[ \Theta_{n-3}^{[d]} = (-1)^{n-3} \left( \pi - \cos^{-1} \left( \frac{||x_3^{[d]}||}{2} \right) \right). \]

From Eqs. (31) and (32), matrix \( W_1^{[d]} \) is fixed as
\[ W_1^{[d]} = T \left( \Theta_{n-2}^{[d]} \right), \quad d \in (0, 1), \]
(39)
Thus, the number of free parameters is reduced.

From the relation \( x_3^{[d]} = ||x_3^{[d]}|| T(\Theta_{n-3}^{[d]}) x_2^{[d]} \) with Eq. (32), we have
\[ W_2^{[d]} = \frac{1}{||x_2^{[d]}||} \times \left( I + \sum_{k_d=1}^{N_d-3} \prod_{n_d=3}^{N_d-k_d} W_n^{[d]} + \frac{1}{2} U_0^{[0]} V^{[d]} \right) T(\Theta_{n-3}^{[d]}), \]
(40)
or equivalently
\[ \Theta_{n-2}^{[d]} = -\tan^{-1} s_d(\Theta) c_d(\Theta)^2 + \Theta_{n-3}^{[d]}, \quad d \in (0, 1), \]
(41)
where we used the fact that a linear combination of rotation matrices is represented by a scaled rotation matrix. Although \( ||x_3^{[d]}|| \) depends on matrices \( W_1^{[d]} \) and \( W_2^{[d]} \), it is solvable after the process for \( d = 1 \).

In summary, the first-order vanishing moment constraint in Eq. (7) reduces one parameter since matrix \( W_0^{[0]} \) depends on other matrices, where the angle \( \Theta_{n}^{[0]} \) is imposed to be \( \Theta_{n}^{[0]} = \sum_{d=0}^{N_d} \sum_{n_d=3}^{N_d} \Theta_{n_d}^{[0]} \). Additionally, the second-order vanishing moment constraint reduces four parameters for matrices \( W_1^{[1]}, W_2^{[1]}, W_1^{[0]}, W_2^{[0]} \). In total, the number of parameters to be freely chosen results in \( N_0 + N_1 - 3 \). For \( N_0, N_1 > 3 \), however, we have to take special care of the lengths of vectors \( x_3^{[0]} \) and \( x_3^{[1]} \). They must be constrained to be shorter than two. Under this constraint, we are allowed to control \( U_0^{[0]} \) and \( W_{n_d}^{[d]} \) for \( n_d = 3, 4, \cdots, N_d, d \in (0, 1) \).

3.3 Alternative Parameterization with Flipping

The previous discussion restricts all controllable matrices to be in the rotation form. Experimentally, other forms of parameterization is often favorable. We here briefly summarize an alternative parameterization.

It is allowed to rewrite \( V_n^{[0]} \) for \( N_0 \geq 2 \) in Eq. (25) as
\[ V_n^{[0]} = J \prod_{n_{i}=1}^{N_1} W_{n_{i}}^{[1]} \prod_{m_{i}=3}^{N_d} W_{m_{i}}^{[0]}, \]
(42)
where \( J \) is the \( 2 \times 2 \) counter identity matrix, i.e., \( \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \), and used instead of \( T(\pi/2) \). Note that matrix \( J \) is orthonormal, but not rotational as in Eq. (21).
Let us parameterize $W_{N_0}^{(d)}$ as $J W_{N_0}^{(d)}$ with a rotation matrix $W_{N_0}^{(d)}$. Then, we can modify Eqs. (25) and (26) as

$$V^{[1]} = J W_{N_1}^{(1)} \prod_{n=3}^{N_1-1} W_{n_1}^{(1)},$$

$$V^{[0]} = J T W_{N_0}^{(0)} \prod_{n_1=1}^{N_0-1} W_{n_1}^{(0)} W_{n_0}^{(0)},$$

where the relation $J T[\theta] J = T[\theta]^T$ is used.

It is easy to see that if $U_0^{(0)}$ is parameterized as $U_0^{(0)} J$ with a rotation matrix $U_0^{(0)}$, matrix $J$ vanishes from Eq. (33). As a result, the same discussion follows as the previous subsection, except that $\theta_U^{(0)} + \theta_V^{(0)}$ in Eqs. (36) and (37) is given by

$$\theta_U^{(0)} + \theta_V^{(0)} = \frac{\theta_0^U + \theta_1^V}{\sum_n \theta_n^U},$$

where $\theta_U^0$, $\theta_N^0$ and $\theta_{N_1}^1$, are the rotation angles of matrices $U_0^{(0)}$, $W_{N_0}^{(0)}$, and $W_{N_1}^{(1)}$, respectively. Note that the first-order vanishing moment imposes the angle $\theta_W^{(0)}$ of matrix $W_0^{(0)}$ to be $\theta_W^{(0)} = (\theta_{N_1}^1 + \sum_n \theta_n^1) - (\theta_{N_0}^0 + \sum_n \theta_n^0)$. The number of parameters still remains $N_0 + N_1 - 3$.

4. Design Examples

In this section, we start with introducing the autocorrelation function (acf). Using the acf, we optimize some filter banks in terms of coding gain and show design examples, which have the first or second-order vanishing moments. In order to verify the significance of the vanishing moments, we compare frequency responses. Moreover, we confirm the symmetry from basis images. Through experiments, we compare the coding performance.

4.1 Autocorrelation Function (acf)

Let us define $x(n)$ as a pixel value at a location $n$, where $n$ is a 2-D integer vector, $n \in Z^2$. Then let us define a continuous vector $p = (p_0, p_1)^T \in R^2$, and assume that pixel $x(n)$ is sampled as $x(p)_{|p=n}$ from a 2-D continuous function $x(p)$.

A natural image $x(p)$ can often be modeled as a stational, zero-mean 2-D continuous-space random field $\tilde{x}(p)$ of which acf

$$R_{\tilde{x}}(\tau) = E[\tilde{x}(p + \tau)\tilde{x}(p)]$$

doesn’t depend on the location $p$ but only distance $\tau \in R^2$.

In our design examples of M-D filter banks, the following separable model is assumed:

$$R_{\tilde{x}}(\tau) = \rho_0 |\tau_0| \rho_1 |\tau_1|,$$  \hspace{1cm} (44)

where $|\rho_0|, |\rho_1| < 1$ and $\tau_0$ and $\tau_1$ are elements of distance $\tau$.

4.2 Design Examples and Coding Application

In the following design examples, the filter banks are optimized for maximizing coding gain, for the separable acf model in Eq. (44) with $\rho_0 = \rho_1 = 0.95$. We employed different optimization methods for the case of 1st-order and 2nd-order vanishing moments. For the 1st-order constraints or the 2nd-order case with $N_0, N_1 < 4$, we employed the unconstrained non-linear optimization function ‘fminunc’ in MATLAB R2008a. On the other hand, for the 2nd-order case with $N_0, N_1 > 3$, we employed the constrained non-linear optimization function ‘fmincon’ in MATLAB R2008a. For every case, the best result among several trials

of optimization process with randomly initialized parameters is selected to be shown.

Figures 3 and 4 are frequency responses and basis images of the minimal support design of size $6 \times 6$. As well, Figs. 5 and 6 show those of size $8 \times 8$.

Figure 7 shows the frequency responses of the resulting analysis filters of size $12 \times 12$ taps designed with the constraint of the second-order vanishing moments for $\rho_0 = \rho_1 = 0.95$, where the non-linear constraint functions $\|x_0^{[0]}\| < 2$ and $\|x_1^{[1]}\| < 2$ are used for the constrained optimization process.

$H_{00}(z)$ and $H_{01}(z)$ became a lowpass and highpass filter, respectively. From the paraunitary property, the impulse responses of the synthesis filters $F_{k\ell}(z)$ are given as the $180^\circ$-rotated version of these analysis filters $H_{k\ell}(z)$. Figure 8 shows an example with only the first-order vanishing moments of which size is $12 \times 12$ for $\rho_0 = \rho_1 = 0.95$. It is observed that the lowpass filter $H_{00}(z)$ shown in Fig. 7 is smoother than that in Fig. 8 at every aliasing frequency point as expected.

As well, we show basis images of designed filter banks. Figures 9 and 10 correspond to Figs. 7 and 8, respectively. It can be confirmed that the filter banks satisfy the symmetry.

The coding gains of filter banks are shown in the Table 1.

Fig. 11  Experimental results of image coding (5-level DWT, 0.5[bpp]).

(a) Original Lena image  (b) second-order vanishing moments, $12 \times 12$ taps, $\rho_0 = \rho_1 = 0.95$

(c) first-order vanishing moments, $12 \times 12$ taps, $\rho_0 = \rho_1 = 0.95$  (d) 9/7DWT
For all design cases, the coding gain of filter banks with the 2nd-order vanishing moments shows lower value than that of the 1st-order one. It is natural because the constraints reduce the number of free parameters. Although the filters in Fig. 7 is imposed the second-order vanishing moments, the coding gain approaches to that of the filters only with the first-order vanishing moments.

### 4.3 Application to Image Coding

In order to verify the significance of the second-order vanishing moments, we show some results of image coding experiments.

In the experiments, we used five-level DWTs, and apply them to coding of Lena image (512 × 512, 8-bit, grayscale) and Barbara image (320 × 240, 8-bit, gray-scale). In the transform domain, we applied the entropy coded scalar quantization (ECSQ) [1]. Figure 11 (a) shows part of the original Lena image. Reconstructed images are shown in Figs. 11 (b)(c) and (d), where subband quantization at average 0.5[ppp] is applied. Figures 11 (b) and (c) are obtained through 5-level DWTs with the filter banks corresponding to Figs. 7 and 8, respectively. For reference, the result of 9/7 DWT is shown in Fig. 11(d). Comparing Figs. 11(b) and (c), some structural artifacts are clearly noticed in (c), whereas they are suppressed in (b). The experimental results of Barbara image are shown in Fig. 12. As well as Lena in Fig. 11, the structural artifacts in (c) are suppressed in (b). PSNR results of our designed filter banks with the 5/3 and 9/7 DWT are summarized in Table 2. Almost all of results of the filter banks with the 2nd-order vanishing moments work better

than 1st-order. The second-order vanishing moments make the smoothness of reconstructed images better. However, the performance of our designed filter banks is inferior to that of 9/7 DWT. We consider that our filter banks require more vanishing moments or directional characteristics.

5. Conclusions

In this paper, a design method of 2-D orthogonal symmetric wavelets was proposed by using a lattice structure for M-D LPPUFB, which the authors have proposed before and Lu Gan et al. have modified later. The derivation process of the constraints on the second-order vanishing moments was shown and some design examples obtained through optimization with the constraints were shown. By using the designed filter banks, we verified the significance through experimental results of image coding. In future, we will consider increasing the order of vanishing moments and investigate the filter directionality.
