SUMMARY Location theory on networks is concerned with the problem of selecting the best location in a specified network for facilities. In networks, the distance is an important measure to quantify how strongly related two vertices are. Moreover, the capacity between two vertices is also an important measure. In this paper, we define the location problems called the $p$-center problem, the $r$-cover problem and the $p$-median problem on undirected flow networks. We propose polynomial time algorithms to solve these problems.

1. Introduction

Location theory on networks is concerned with the problem of selecting the best location in a specified network for facilities. Many studies for the theory have been done. Most of these studies treat location problems on networks from the standpoint of measuring the closeness between two vertices by the distance between two vertices. On the other hand, location problems on networks from the standpoint of measuring the closeness between two vertices by the capacity (maximum flow value) between two vertices have not been studied yet.

This paper concerns location problems on undirected flow networks. We define the location problems called the $p$-center problem, the $r$-cover problem and the $p$-median problem on undirected flow networks. We propose polynomial time algorithms to solve these problems.

2. Definitions

Let us consider an undirected flow network $N=(V, E, w_F)$ such that $V$, $E$ and $w_F$ are the vertex set, the edge set and the function assigning a positive real number $w_F(e)$, called edge-capacity, to each edge $e$ of $E$, respectively. The capacity of minimum cutset between two vertices $x$ and $y$ in $N$ is called the capacity between $x$ and $y$, denoted by $g(x, y)$. Especially, let $g(x, x) = \infty$.

For a subset $U$ of $V$, let

$$g(U, x) = \max\{g(x, y) | y \in U\}$$

and

$$\epsilon_b(U) = \min\{g(U, x) | x \in V\}.$$  

$\epsilon_b(U)$ is called the eccentricity of $U$ which is concerned with capacity (we simply call $\epsilon_b(U)$ the eccentricity of $U$, hereafter).

For $1 \leq p \leq |V|$, a subset $U$ of $V$ such that $|U| = p$ and $\epsilon_b(U) = \max\{\epsilon_b(U') | U' \subset V, |U'| = p\}$ is called a $p$-center of $N$. We simply call the problem of finding a $p$-center the $p$-center problem.

For a positive real number $r$, let

$$\delta_b(r) = \min\{|U| | U \subset V, \epsilon_b(U) \geq r\}.$$  

A subset $U$ of $V$ such that $\epsilon_b(U) \geq r$ and $|U| = \delta_b(r)$ is called a $r$-cover of $N$. We simply call the problem of finding a $r$-cover the $r$-cover problem.

Let

$$t_b(U) = \sum_{x \in U} g(U, x).$$  

$t_b(U)$ is called the transportation number of $U$.

For $1 \leq p \leq |V|$, a subset $U$ of $V$ such that $|U| = p$ and $t_b(U) = \max\{t_b(U') | U' \subset V, |U'| = p\}$ is called a $p$-median of $N$. We simply call the problem of finding a $p$-median the $p$-median problem.

In a communication network, vertices represent terminal computers and edges represent links between computers. In this network, consider how we assign some data to files. We assume that the delay time can be ignored in this network. In this case, for each terminal computer pair, the number of links between the computers is the measure representing the closeness between the computers. Location theory on flow networks is applicable to the above case.

For example, let us consider the network $N$ shown in Fig. 1 where the value attached to each edge represents the edge capacity. Let $U$ be $\{x_1, x_2\}$. Since

$$g(U, x_1) = g(x_1, x_2) = 6,$$

$$g(U, x_2) = g(x_1, x_2) = 5$$

and

$$g(U, x_3) = g(x_1, x_2) = 6,$$

the eccentricity and the transportation number of $U$ are following.

For example, let us consider the network $N$ shown in Fig. 2(a). Then, a tree flow network $T$ such that $g_T(x, y) = g_T(x, y)$ for any vertex pair is shown in Fig. 2(b). So we consider location problems on tree flow networks for flow networks, hereafter.

3. Results

3.1 The $p$-Center Problem and the $r$-Cover Problem

This section concerns the $p$-center problem and the $r$-cover problem.

[Theorem 1] Let $T$ be a tree flow network with $E(T) = \{(x_0, y_1), \ldots, (x_n, y_m)\}$ such that $w(x_0, y_1) \geq \cdots \geq w(x_n, y_m)$ and let $T_1, \ldots, T_p$ be all connected components of $T' = T - (x_{m-p+1}, y_{m-p+1}) \ldots, (x_n, y_m)$. Then, $U = \{z_1, \ldots, z_p\}$ is a $p$-center of $T$, where $z_i \in V(T_i)$ for each $i, 1 \leq i \leq p$.

(proof) Let $w(x_{m-p+1}, y_{m-p+1}) = a$. For any $x \in V(T)$, $g(U, x) \geq a$, because $g(x, z_i) \geq a$ if $x$ belongs to a connected component $T_i$. Let $T_i$ be a connected component that includes an edge $(x_{m-p+1}, y_{m-p+1})$. Without loss of generality, we may assume that $z_i$ belongs to a connected component including $x_{m-p+1}$ in $T_i = (x_{m-p+1}, y_{m-p+1})$. Since $g(U, y_{m-p+1}) = g(z_i, y_{m-p+1}) = a$, $e_T(U') = a$. The eccentricity of $U$ does not depend on how to choose $z_i$ in each connected component $T_i$ and the value is $a$. Let $U'$ be a subset of $V(T)$ and $|U'| = p$. We assume that there exists a connected component $T_i$ such that $V(T_i) \cap U' = \emptyset$ in $T'$. Since, for a vertex $x$ in $T_i$ and each element $z$ in $U'$, the path from $x$ to $z$ in $T$ includes an edge $(x_{m-p+1}, y_{m-p+1})$ or an edge $(x_{m-p+2}, y_{m-p+2})$ or ... or an edge $(x_n, y_n)$, $e_T(U') \leq a$. Therefore $U$ is a $p$-center of $T$.

For example, let us consider the network $T$ shown in Fig. 2(b) and let $p = 3$. The subnetwork $T_{p-1}$ is obtained by deleting the edge set $\{(x_1, x_2), (x_3, z_1)\}$ (see Fig. 3). Therefore, from Theorem 1, $U = \{x_1, x_2, x_3\}$ is a 3-center of $T$.

The time complexity of sorting all edges in order of size of edge weights is $O(|V| \log |V|)$, where $|V| = |V(T)|$. We can choose $U$ in $O(|V|)$ time from $T'$ by depth-first search$^{18}$. Therefore, a $p$-center of a tree flow network $T$ can be obtained in $O(|V| \log |V|)$ time.

[Theorem 2] Let $T$ be a tree flow network and let $T_1, \ldots, T_q$ be all connected components of $T' = T - (x, y) \in E(T)$ such that $w(x, y) \leq r$. Then, $U = \{z_1, \ldots, z_q\}$ is an $r$-cover of $T$, where $z_i \in V(T_i)$ for each $i, 1 \leq i \leq q$.

(proof) Clearly, $e_T(U) \geq r$. Let $U'$ be a subset of $V(T)$ such that $|U'| < r$. Then, there exists $T_i$ such that $V(T_i) \cap U' = \emptyset$ in $T'$. Since, for a vertex $x$ in $T_i$ and each element $z$ of $U'$, the path from $x$ to $z$ in $T$ includes an edge whose weight is less than $r$, $g(U', x) < r$. Therefore $e_T(U') < r$. So $U'$ is a $r$-cover.

For example, let us consider the network $T$ shown in Fig. 2(b) and $r = 5$, edges whose weights are less than 5 are $(x_1, x_2), (x_4, x_3)$ and $(x_5, x_6)$. So, the
subnetwork $T'$ is obtained by deleting these edges (see Fig. 4). Therefore, from Theorem 2, $U = \{(x_2, x_3, x_4, x_5)\}$ is a $5$-cover of $T$.

The time complexity of constructing $T'$ is $O(|V|)$. The time complexity of choosing $U$ is $O(M)$. Therefore, a $r$-cover of a tree flow network $T$ can be obtained in $O(|V|)$ time.

From Theorem 1 and Theorem 2, a $p$-center and a $r$-cover of a flow network, which is not necessary a tree, can be obtained in $O(|V|)$ time.

3.2 The $p$-Median Problem

This section concerns the $p$-median problem. In an undirected flow network $N$, let

$$s_p = \max_t(t_p(U) | U \subseteq V, |U| = p).$$

[Theorem 3] Let $T$ be a tree flow network and $(x_2, x_3)$ be a minimum weight edge of $T$. In $T - \{(x_2, x_3)\}$, let $T_1$ be the connected component that includes $x_2$ and $U \subseteq V(T_1)$ ($i = 1, 2, \ldots, p$).

Then $t_p(U_1 \cup U_2) = t_p(U_1) + t_p(U_2)$.

(proof) From the property of trees, $g(x, y)$ is the minimum value of edge such that the edge belongs to the path $P$ from $x$ to $y$. Since $(x_2, x_3)$ is a minimum weight edge of $T$, $g(x, y) \geq g(x_2, x_3)$.

Let $V(T) - (U_1 \cup U_2) = \{x_1, \ldots, x_4\}$.

$$t_p(U_1 \cup U_2) = \sum_{i=1}^{n-p} g(U_1 \cup U_2, x_i)$$

$$= \sum \max \{g(U_1, x_i), g(U_2, x_i)\}.$$  

If $x_i \in V(T_1)$ then $g(U_2, x_i) = g(x_2, x_i)$. Hence $g(U_1, x_i) \geq g(U_2, x_i)$.

If $x_i \in V(T_2)$ then $g(U_2, x_i) \leq g(U_2, x_i)$. Therefore

$$= \sum \max \{g(U_1, x_i), g(U_2, x_i)\}$$

From Theorem 3, the transportation number of a subset of $V(T)$ is equal to the sum of the transportation numbers in each connected component in $T - \{(x_2, x_3)\}$. Therefore, in the case of given $s_{r_1}(1), s_{r_1}(2), \ldots, s_{r_1}(k), s_{r_2}(1), \ldots, s_{r_2}(l)$ where $t_i = \min \{p_i \leq |V(T_i)| \}$ \((i = 1, 2, \ldots, n)\), $s_r(p)$ is given by the following expression.

$$s_r(p) = \max \{s_{r_1}(k) + s_{r_2}(p - k), s_{r_1}(t_i + 1) + s_{r_2}(p - t_i - 1), \ldots, s_{r_1}(p - t_2) + s_{r_2}(t_2)\},$$

where $s_r(0) = \min \{p_i \leq |V(T_i)| \}$ \((i = 1, 2, \ldots, n)\).

Hence, if $i$-medians of $T_1$ \((i = 1, \ldots, k)\) and $j$-medians of $T_2$ \((i = 1, \ldots, l)\) are given, then we can obtain a $p$-median of $T$.

For example, let us consider the network $N$ shown in Fig. 2(b) and let $p = 3$. The minimum weight edge of $T$ is $(x_2, x_3)$ and its value is 2. In $T - \{(x_2, x_3)\}$, let $T_1$ be the connected component that includes $x_4$ and $T_2$ be the connected component that includes $x_7$ (see Fig. 5). $t_i = \min \{p_i \leq |V(T_i)| \}$ = minimize $3$ and $t_2 = \min \{3, 2\} = 2$. $s_{r_1}$ and $s_{r_2}$ are given as follows.

$$s_{r_1}(0) = w(x_4, x_3) \cdot |V(T_1)| = 2 \times 6 = 12,$n$$

$$s_{r_1}(1) = 27 \cdot \{t_{r_1}(x_2)\} = 27,$n$$

$$s_{r_1}(2) = 23 \cdot \{t_{r_1}(x_1, x_3)\} = 23,$n$$

$$s_{r_1}(3) = 18 \cdot \{t_{r_1}(x_1, x_3, x_5)\} = 18,$n$$

$$s_{r_2}(0) = w(x_4, x_3) \cdot |V(T_2)| = 2 \times 2 = 4,$n$$

$$s_{r_2}(1) = 4 \cdot \{t_{r_2}(x_7)\} = 4,$n$$

$$s_{r_2}(2) = 0 \cdot \{t_{r_2}(x_7)\} = 0.$n$$

From above values, we can obtain $s_r(3)$.

$$s_r(3) = \max \{s_{r_1}(3) + s_{r_2}(0), s_{r_1}(2) + s_{r_2}(1), s_{r_1}(1) + s_{r_2}(3)\}$$

$$= \max \{18 + 4, 23 + 4, 27 + 0\}$$

Fig. 5 A network $T - \{(x_2, x_3)\}$.  

\[ T_1 \]

\[ T_2 \]
Therefore, \((x_1, x_2) \cup (x_2, x_3)\) is a 3-median of \(T((x_2) \cup (x_2, x_3)\) is also a 3-median of \(T\).

The following algorithm SUB-MEDIAN \((p, T_1, T_2, (z_1, z_2))\), where \(p \leq |V(T_1) \cup V(T_2)|\), \(z_i\) belongs to \(T_i\) \((i = 1, 2)\) and \((z_1, z_2)\) is a minimum weight edge of \(T\), is the algorithm to obtain a \(p\)-median of \(T\) \((= T_1 \cup T_2 + (z_1, z_2))\), when each \(j\)-median Set\(_T\) \((j)\) and its transportation number \(s_T(j)\) of \(T\) are given.

**procedure** SUB-MEDIAN \((p, T_1, T_2, (z_1, z_2))\)

\begin{align*}
S_1 & \quad s_T(0) := w(z_1, z_2)|V(T)|; \\
S_2 & \quad s_T(0) := w(z_1, z_2)|V(T_2)|; \\
S_3 & \quad t_1 := \min(|V(T_1)|, p); \quad t_2 := \min(|V(T_2)|, p); \\
S_4 & \quad s_0 := 0; \quad t_0 := 0; \\
S_5 & \quad \text{for } j = p - t_2 \text{ to } t_1 \text{ do} \\
& \quad \text{begin} \\
& \quad \quad s_0 := s_T(j) + s_T(p - j) \\
& \quad \quad t_0 := s_T(j) + s_T(p - j); \\
& \quad \quad t_0 := j; \\
& \quad \text{end} \\
S_9 & \quad s_T(p) := s_0; \\
S_{10} & \quad \text{Set}_T(p) := \text{Set}_T(0) \cup \text{Set}_T(p - 0). \\
\end{align*}

(*) Set\(_T(p)\) represents a \(p\)-median of \(T\) (*)

Since \(S_5\) requires \(O(p)\), the time complexity of SUB-MEDIAN is \(O(p)\).

Using above algorithm, a \(p\)-median of a tree flow network \(T\) can be obtained by the following algorithm MEDIAN \((T, p)\)

**procedure** MEDIAN \((T, p)\)

\begin{align*}
M_1 & \quad \text{sort all the edges in order of size of edge weights; } (* \text{ let } w(x_1, y_1) \leq \cdots \leq w(x_m, y_m) * ) \\
M_2 & \quad \text{let } T_0 \text{ be a null network whose vertex set is } V(T); \\
M_3 & \quad \text{for } x \in V(T) \text{ do} \\
& \quad \text{begin} \\
& \quad \quad \text{component includes } x \text{ in } T_0; \\
M_5 & \quad \quad \text{end} \\
M_6 & \quad \text{for } i = 1 \text{ to } m \text{ do} \\
& \quad \text{begin} \\
M_7 & \quad \quad \text{let } T_{xi} \text{ be the connected component includes } x_i \text{ in } T_0; \\
M_8 & \quad \quad \text{let } T_{yi} \text{ be connected component includes } y_i \text{ in } T_0; \\
M_9 & \quad \quad t := \min(p, |V(T_{xi})| + |V(T_{yi})|); \\
M_10 & \quad \quad \text{for } k = 1 \text{ to } t \text{ do} \\
M_11 & \quad \quad \text{SUB-MEDIAN } (k, T_{xi}, T_{yi}, (x_i, y_i)); \\
M_12 & \quad \quad T_0 := T_0 + ((x_i, y_i)). \\
& \quad \text{end} \\
& \quad \text{end.}
\end{align*}

In \(M_1\), sorting of edges requires \(O(|V| \log |V|)\) where \(|V| = |V(T)|\). \(M_6, M_10\) and \(M_11\) require \(O(|V|)\), \(O(p)\), and \(O(p)\), respectively. Therefore the time complexity of MEDIAN is \(O(|V| \log |V| + p^2 |V|)\). So, a \(p\)-median of a flow network \(N\), which is not necessary a tree, can be obtained in \(O(|V| s(|V|, |E|))\) time.

4. Conclusion

In this paper, we have given the definitions of location problems on undirected flow networks and we have proposed the \(O(|V| s(|V|, |E|))\) time algorithms to solve the \(p\)-center problem, the \(r\)-cover problem and the \(p\)-median problem on an undirected flow network \(N\), where \(|V| = |V(N)|\), \(|E| = |E(N)|\) and \(s(|V|, |E|)\) is the time required to solve a maximum flow problem in \(N\). The algorithms to solve these problems are applicable to the assignment of files in a computer network, where the vertices represent terminal computers and the edges represent links between computers.

For a directed flow network \(N\), there does not always exist a tree flow network \(T\) such that \(g_N(x, y) = g_T(x, y)\) for any vertex pair. So, the same discussion as in this paper does not apply to directed flow networks. The study of location problems on directed flow networks is a future problem.
